BEFORE ANYONE ARRIVES

- Laptop: **/dashboard** fronted. Tabs open: **/replay**, **/public?s=5**.
- Phone: **/entry**, PIN 1111, storage cleared so it reads "0 today".
- **/demo** -> Clear the board, then Start outbreak on sector 5.
- Check the alert actually appears before you relax.
- Referral card + pilgrim QR poster face up on the table.

Redo the last three steps every 30-45 minutes. The traffic cron keeps generating patients and the board slowly fills - correct behaviour, but it looks like noise to someone seeing it cold.

WHO DOES WHAT

- **Greeter** - speaks, hands over the phone, watches for the next arrival.
- **Driver** - at the laptop, clicks only what the greeter narrates.
- **Other two** - one step back, silent, ready to take the next judge.

Never let two people answer one question. Correct each other after the judge leaves, not in front of them.

LAYER 0 - FIRST 15 SECONDS

> **"At the Kumbh, fourteen people drink from a cracked pipe. They go to four different clinics at four different hours, so every doctor sees three or four cases of diarrhoea - a normal Tuesday. Nobody raises an alarm, because the number fourteen doesn't exist anywhere. We built the thing that adds it up, every five minutes."**

Then stop, and ask them:

> **"Do you want the thirty-second version, or the technical one?"**

That question hands them control, tells you which branch to take, and stops you making a speech at someone who wanted a conversation.

LAYER 1 - 60 SECONDS, ONE SCREEN

Turn the laptop toward them. Point at three things, no more.

- **The sector map.** "Twelve sectors, seventeen clinics, live. Grey means a sector stopped reporting - different from calm."
- **The alert.** Click it. "Every alert shows its arithmetic. An officer can argue with this - they ignore anything they can't argue with."
- **Dispatch.** "It becomes a job a named crew must close with what they found. That's why time-to-response is a number, not a claim."

> **"Everybody else builds the dashboard. We built the ten minutes after it."**

LAYER 2 - HAND THEM THE PHONE

The strongest move at a table. Do not demo the phone - **give it to them.**

> **"Log a patient. You're the doctor."**

Say nothing while they tap. Then: **"That took ten seconds and you'd never seen it before."** Point at the laptop - the tile has moved.

Then the two things they will not have thought of:

- **It works with no network.** Queues on the phone, syncs later. If the form is slow on a bad network, doctors abandon it by day three and every other screen goes dark.
- **A second signal.** Medicine stalls tally sales. Different reporter, different act, different failure modes. "Two signals agreeing is evidence. One signal shouting twice isn't." It also catches people who never reach a clinic at all.

> **Volunteer it: "In this demo both streams are simulated and one command writes both. You're seeing the architecture, not the evidence for it."**

LAYER 3 - PICK ONE BRANCH

TECHNICAL judge - go to the harness. Your strongest card; almost no team has one.

> **"We didn't want to assert it works, so we measured it. A thousand synthetic festivals, an outbreak at a random sector and hour, running the deployed detection function over every hour."**

- Imports the live **scoreCell()** - not a copy that could drift.
- Seeded: **--seed 42** reproduces on their machine.
- Mirrors the engine's dedup, so one outbreak isn't six catches.
- False-alarm half has **nothing injected** - cannot be gamed.

Result: typical outbreak caught every time, median 7h, at **8 cases vs 33** unaided. **Offer to run it in front of them** - `node eval/harness.mjs`. Offering is worth nearly as much as running it.

If they push on the maths, say the whole detector out loud: **"Observed minus the mean, over the max of the standard deviation, the square root of the mean, and one. Fires at three, minimum eight cases."** Then the Poisson floor - three quiet days give a standard deviation of zero, z goes infinite, every cell screams. That one term kills most small-sample false alarms.

PUBLIC HEALTH judge - go to the pilgrim screen.

> **"It shows which areas are affected and which illness is going around. It never shows a case count. A number invites comparison, comparison moves crowds, and crowd movement is what kills at these events."**

Then the card: the QR carries **the record itself, not a link** - a village clinic reads it with no network and no app. If they know the history, name it first: Harvard 2015 proved workers will enter the data (2,000 visits day one), then drew charts with it - 31% antibiotics, recorded and never acted on.

BUSINESS judge. "Nothing here is ours to keep alive - static assets and two Cloudflare Workers, no server to scale on a bathing day. And it's config-driven: point it at a different gathering by editing one file. No new hardware, no new staff - we ask for ten seconds of what the doctor already knows."

ANSWERS - KEEP THEM TO 3 SENTENCES

"Isn't this just a dashboard?"

A dashboard is where this stops for everyone else. Ours turns every alert into an assigned job a named crew must close - the only reason time-to-response is measurable at all.

"Why no AI?"

An officer acts on "fourteen against four expected" and ignores a black box. And 72 series with no labelled outbreak history gives a model nothing to learn that arithmetic doesn't already give you.

"Your data is fake." - say it first

Yes. Synthetic, written through the same API a real tablet uses, so the detector can't tell. That's what let us measure across a thousand festivals instead of asserting it once.

"What about a bathing day?" - concede instantly

Correct, and the first thing we'd fix. We detect on raw counts, so a real surge false-positives everywhere. Fix is rates per thousand present. Designed, deliberately not built.

"Three sigma - one-in-740?" - do NOT say yes

No. It's a triage threshold, not a p-value - tuned to put the right number of things in front of a human, which is why we measured the false-alarm rate instead of quoting a tail probability.

"Why not scan Aadhaar?"

Aadhaar holds demographics, not medical history - ABHA is the one that holds records. But identity adds nothing: a z-score doesn't care who anyone is. It would cost the ten-second entry and turn away the elderly and rural pilgrims most at risk.

"How many false alarms?"

1.5/day dispatch a crew, 5.4/day are dashboard-only. Reported separately because they cost different things. Caveat honestly: that's Poisson traffic, our own simulator is burstier and fires more.

"What's left to build?"

Crowd normalisation, clinician review of the advice, native-speaker check of the Hindi and Marathi, and validation against the real Jana Swasthya dataset. All written down, none hidden.

"Who built what?"

Have a real answer. Name who did pitch, content, testing, engineering. Never "we all did everything."

SIX RULES OF THE TABLE

- **Read every number off the screen.** Say 14 when it shows 34 and you have lost them for good.
- **Never be seen typing a URL.** Everything is one click from an open tab.
- **Hand over the phone.** A judge who used it remembers it; one who watched you use it remembers nothing.
- **Say the weakness first.** Volunteering a limitation buys more than defending one costs.
- **Stop talking when they start.** A question is interest.
- **Never quote "600 reduced to 35."** Fitted to nothing, and it sits beside a measured number.

IF IT BREAKS

- No alert -> **/demo** Start outbreak. Still nothing -> **/replay**.
- Board stale -> Ctrl+Shift+R. **Never deploy during judging.**
- Phone won't sync -> "It's queued. That's the offline design." True.
- Board noisy -> Clear the board, Start outbreak. Ten seconds.
- Laptop dead -> talk. Layer 0 and the card work with no screen.

> **If you get one sentence: "Every clinic treats its own patients well and nobody compares notes. We do that every five minutes - and we catch a typical outbreak at eight cases instead of thirty-three, about seven hours earlier."**
